COVID-19 detection on chest x-ray using an enhanced neural network model: Impact of data network complexity, data augmentation, and transfer learning

Himal Bamzai-Wokhlu

Buchholz High School, United States

Statement of the Problem: Machine learning (ML) algorithms have potential to rapidly screen COVID-19 from chest x-ray (CXR). Current deep convolutional neural network (DCNN) models for COVID-19 detection are limited by small datasets and are prone to over fitting. To optimize such a model, we assessed the performance impact of network complexity, data augmentation, and transfer learning on model performance.

Methodology & Theoretical Orientation: A DCNN model was developed using the COVID open access dataset of 16,352 CXR images associated with known COVID-19 status by RT-PCR. Performance characteristics of pre-trained CNNs, 24 models in all, with various enhancement features were compared.

Findings: Among 5 pertained DCNNs, low complexity ResNet18 architecture performed best. Increasing complexity correlated with validation loss. Adding data augmentation using horizontal flip (HF), Gaussian blurs (GB), and cut out (CO) improved ResNet18 performance—with the ResNet18-CO/GB model performing best at 1,000 iterations. Transfer learning using a tuberculosis (TB) detection model enhanced the performance of ResNet18-HF and ResNet18-CO/HF/GB models, while transfer learning using a pneumonia dataset for pertaining did not improve model performance. At 10,000 iterations, the best model for COVID-19 detection was ResNet18-GB/CO, with a sensitivity of 82.0%, specificity 96.5%, positive predictive value 81.8%, negative predictive value 95.0%, F-score 81.5%, and accuracy 94.5%. Validation loss was low overall at 0.18, but mild over fitting was observed with validation-training loss difference of 0.06. This robust final COVID-19 CXR detection model meets the World Health Organization standards for COVID-19 antigen tests (sensitivity>80%, specificity>97% and exceeds the <50% sensitivity and <80% specificity achieved by unassisted radiologists. Transfer learning models did not perform as well as the data augmented DCNNs.

Conclusion & Significance: Our findings suggest there is clinical utility for automated COVID-19 detection by CXR, particularly if data augmentation is heavily incorporated into such models.

Sustainable textiles industries in brand technology between technologies of brands

Elsayed A. Elnashar

Kafrelsheikh University, Egypt

Sustainable textiles industries in brand technology between technologies of production brands, the technology industry thrives on change, requiring constant experimentation and innovation. Rather than deterring new entries, highly saturated markets beckon for potentially technology products and ideas. other hand; To stimulate customer loyalty and differentiate from competitors, tech brands strive to continually deliver technology software updates of textiles, communicate novel use cases or launch new systems of textiles technology and brand if textiles; to know how strategic tech company branding and marketing can help your company generate a competitive advantage in this fast-moving space.

Biography

Elsayed Ahmed Elnashar is a full-professor of textiles apparel in Kafrelsheikh University, Egypt. He was born on 19/8/1965. He did his Ph.D in the year 2000, M. Sc in 1995, B. Sc in 1989 from Helwan University and Diploma in 1985 from the Advanced Industrial Textiles Institute. He holds several academic administrative positions: Dean, Vice Dean, Head of Department, He has many textiles patents, and is a member of international scientific committees. He has published over 190 scientific articles, funtions as an Editorial board member & reviewer for more than 95 journals, organizer for more than 70 conferences and workshops all over the world. He is the Founder, and editor of two scientific journals and Smartex Conference, Egypt.
