CASE REPORT

Bilateral middle concha bullosa mucopyocele connecting to headache disablement: a case study

ABSTRACT

Concha Bullosa (CB) is the most common anatomic variations of sinonasal anatomy in which the middle nasal turbinate contains pneumatized cells. The most usual variation is concha bullosa in nasal cavity. Sometimes the cause of headache or nasal obstruction is CB. This study describes the case of Computed Tomography (CT) findings of bilateral middle and inferior concha bullosa in a 38-year-old female with nasal obstruction and headache. We obtained paranasal sinuses CT examinations from the Radiology, Ear Nose and Throat of Sifa Hospital in Antalya. The patient was operated victoriously with endoscopic surgery of conchus by Ear Nose and Throat surgeon.

Key Words: Concha bullosa; Sinonasal anatomy; Mucopyocele

INTRODUCTION

Anatomic variations are crucial in preendoscopic computed tomography assessment of the paranasal sinuses. Concha bullosa is a well-known anatomic variant of sinonasal anatomy. CB is defined as an air-filled cavity within the nasal turbinate. Which is the most prevalently present in the inferior turbinate followed by the superior turbinate (1-3). Nasal obstructions or headache can ensue from pressure on the nasal mucosa due to CB which contact with the lateral nasal wall (4). Obstruction of a CB can ensue in a mucocoele. Secondary infections that develop over a mucocoele are assigned to as mucopyoceles (5). We indicated in this case a concha bullosa associated mucopyocele with a large hyperemic nasal mass that induced nasal obstruction and headache. It was successfully treated endoscopically. We also review the utilizable literature.

CASE REPORT

A 38-year-old female with a history of progressive headache and nasal obstruction which had persisted for several years. She was referred to Ear Nose and Throat department of Sifa Hospital in Antalya. The patient that has not got any history of nasal allergy, trauma, or sinus surgery. On nasal endoscopic examination observed enlargement of left and right middle turbinate. Two concha bullosa were located at the postero-superior and postero inferior portions of the left inferior turbinate. Computed Tomography (CT) showed bilateral pneumatization of the middle turbinate and hypertrophy of the left and right middle turbinate. Two concha bullosa were located at the postero-superior and postero inferior portions of the left inferior turbinate. Paranasal sinus tomography (CT) observed a lesion in the left and right nasal cavity similar a mucopyocele in the middle turbinate. A large quantity of purulent was involved in the middle turbinate. The purulent was afterwards aspirated. Staphylococcus Aureus was detected on the culture.

The patient clavulanic acid/amoxicillin treatment was applied for 10 days. Cultures were obtained during the operation. As a result of pathological examination, excision material was described as mucocele. The patient imposed endoscopic middle turbinate surgery under general anesthesia. During the following 7 months post-surgery, the patient’s symptoms had significantly developed and she was no recurrent pathology on her nasal endoscopic examination (Figure 1).

DISCUSSION AND CONCLUSION

Rhinogenic Headache (RH) is among the most common of headaches (6-8). Concha bullosa is the well-known induced of RH and there is frequently an accompaniment septal deviation (9). The term concha bullosa is principally used to characterize pneumatization of the middle turbinate occasionally, of the superior inferior turbinates (10). Concha bullosa is come across both unilaterally and bilaterally and the incidence of it ranges from 14 to 53% (11).

The development of paranasal sinus CT has provided us particular information about this unapproachable area of the middle nasal cavity. Some studies have given an idea that nasal endoscopy disallows ready approach to this area (12). Though the endoscopic examination of the nasal cavity was not indicant given an idea that nasal endoscopy disallows ready approach to this area (12). The principal symptoms were nasal obstruction and headache in our patient. The first person to indicate that middle turbinate was a headache source that needed counseling was Clerio (12). A massive pneumatized middle concha related with headache is very rare. Massive

pneumatization of middle turbinates with accompaniment to mucosal contact can be the induce of headache even in the lack of sinonasal inflammation (14). The aerobic bacteria Staphylococcus Aureus was recognized and it was treated by clavulanic acid/amoxicillin. Additionally, endoscopic concha bullosa resection and drainage were the best alternatives for mucopyoceles treatment at the same time and consequently, the lateral border of the concha bullosa was excised and aspirated the mucopurulent secretion in our case. Finally bilateral middle concha bullosa is not a common anatomic variation. Middle turbinate may not be noticed by endoscopic examination but may be easily recognized on paranasal sinus CT. Paranasal sinus CT scans perform a crucial role in diagnosis and treatment planning because a coronal plain CT of the paranasal sinuses can decided definitely the anatomic variations in this area and their connection to mucosal pathologies. We propose that concha bullosa mucopyoceles should be noted in patients with a large hyperemic nasal mass.
