Case Report

During cadaveric study on the popliteal artery, high division of the popliteal artery was observed on the left side of one of the embalmed male cadaver. This artery divided at the level of upper border of popliteus muscle into an anterior tibial and posterior tibial artery. Inferior lateral genicular artery, which is usually a branch of popliteal artery, was found to be the branch of anterior tibial artery. However, arterial branching pattern and point of bifurcation on the right side were as usual.

Knowledge of these variations will be beneficial to angiographers for evaluation of arteriograms and vascular surgeons for various surgical approaches in the lower extremity.

Abstract

Cadaveric study on the popliteal artery was conducted in the Department of Anatomy, Government Medical College, Patiala. Common variation of high division of popliteal artery was observed on the left side of one of the embalmed male cadaver. This artery divided at the level of upper border of popliteus muscle into an anterior tibial and posterior tibial artery. Inferior lateral genicular artery, which is usually a branch of popliteal artery, was found to be the branch of anterior tibial artery. However, arterial branching pattern and point of bifurcation on the right side were as usual.

Knowledge of these variations will be beneficial to angiographers for evaluation of arteriograms and vascular surgeons for various surgical approaches in the lower extremity.

Key words [popliteal artery] [popliteus muscle] [anterior tibial artery] [posterior tibial artery] [peroneal artery]

Introduction

The popliteal artery is a common recipient site for above or below knee bypass grafts. It is also frequently affected by penetrating and blunt trauma involving the lower extremity. Exposure of this artery is therefore, often required in both emergent and elective vascular procedures [1]. Knowledge of the anatomical variations in the branching of the popliteal artery is important because damage to its branches can be limb- or life threatening [2].

Popliteal artery is the continuation of the femoral artery beyond the tendinous opening in the adductor magnus muscle. Usually, it runs downwards in the popliteal fossa with a lateral inclination superficial to popliteus muscle and terminates by dividing into an anterior tibial and a posterior tibial artery at the lower border of popliteus muscle [3].

The popliteal artery lies on the anterior wall of the popliteal fossa. It gives several branches during its course, i.e., muscular branches pass to the lower parts of the hamstring muscles and to the upper parts of the muscles of the calf. These are large and give rise to cutaneous twigs, one of which accompanies the sural nerve. Two superior (medial and lateral), two inferior (medial and lateral) and middle genicular arteries lie on the on the anterior wall of the popliteal fossa [4].

Received September 4th, 2011; accepted August 11th, 2012

In one case, the popliteal artery coursed deep to the popliteus muscle [1].

Somayaji et al. dissected 250 limbs. In 25 specimens, high division of popliteal artery was seen. In 19 out of 25 specimens, popliteal artery divided at the upper border of popliteus muscle into an anterior tibial and posterior tibial arteries. In 6 specimens, popliteal artery divided at upper border of popliteus muscle into anterior tibial artery and peroneal artery, where the posterior tibial artery was absent [3].

These variants can be explained due to the combination of persistent primitive arterial segments, abnormal
fusions, or segmental hypoplasia or absence, as embryonic vascular development determines the anatomic variability. Thus embryonic vessels may either persist or degenerate (degeneration of these vessels is normal), or abnormal fusions may occur. Understanding the embryology and variant anatomy has significant clinical implications regarding transluminal angioplasty, embolectomy, vascular grafting, direct surgical repair or the diagnosis of the arterial injury [6].

Conclusion
Variations of the branches of popliteal artery are of paramount importance not only in clinical practice but also in theoretical considerations. Knowledge of variation of popliteal artery bifurcation point and branching pattern is mandatory for vascular surgeons to avoid complications during various surgical approaches and the choice of suitable graft sites in lower extremity. Awareness of these variations will also be beneficial to angiographers for evaluation of arteriograms.

Acknowledgement
We are thankful and grateful to our Department Head and Vice Principal Dr. Patnaik VV Gopichand and Dr. Nidhi Puri for their advice and support.
