Mixed tocopherols are better than alpha-tocopherol as anti-oxidants- as good as statins

Zufeng Ding, Tom GP Saldeen, Pankaj Mathur, MD, Jawahar L Mehta, MD, PhD

Atherosclerosis is an inflammatory disease associated with oxidant stress manifested as excess formation of reactive oxygen species (ROS) and high levels of oxidized low-density lipoprotein (ox-LDL) (1-3). Several early epidemiologic studies showed that routine use of vitamin E (as α-tocopherol) resulted in a significant reduction in atherosclerosis-related events. However, subsequent randomized trials of α-tocopherol failed to show any benefit of this therapy (4). It was suggested (5) that α-tocopherol has limited anti-oxidant effect and other constituents of vitamin E, especially γ-tocopherol, might be necessary for the full benefits of vitamin E. Indeed, we demonstrated potent inhibitory effects of γ-tocopherol, more than α-tocopherol, on platelet aggregation and in vivo thrombus formation (6).

Here we describe effects of α- and γ- tocopherol on arterial smooth muscle cells (SMCs)). These cells under the influence of ox-LDL transform into foam cells, and undergo proliferation and migration, express pro-inflammatory adhesion molecules and develop apoptosis-all features of atherosclerotic plaque. Ox-LDL binds to surface receptors, including the lectin-like ox-LDL receptor-1 (LOX-1) in SMCs. LOX-1 activation results in ox-LDL internalization, ROS generation, NF-kB activation, and expression of vascular cell adhesion molecule (VCAM-1) and pro-apoptotic genes (5). Of note, statins have been shown to modify ox-LDL/LOX-1-mediated events (7).

Human primary aortic SMCs were purchased from ATCC (Manassas, VA) and maintained in vascular cell basal medium. SMCs were treated with tocopherols in the absence or presence of simvastatin and ox-LDL for 24 h. Simvastatin, α-tocopherol, γ-tocopherol and δ-tocopherol were purchased from Sigma.

α- and γ-tocopherol inhibited ox-LDL induced LOX-1 expression in a dose-dependent manner, while β-tocopherol alone had no effect and δ-tocopherol a modest effect (Figure 1A). Hence, we focused our studies on the effects of α-, δ-, and γ-tocopherol on LOX-1 expression and its downstream effects on arterial SMCs exposed to ox-LDL (20 µg/ml). Parallel sets of SMCs were treated with simvastatin (10 µM), α-tocopherol and γ-tocopherol alone (10 µM each), or a combination of γ-tocopherol, δ-tocopherol and α-tocopherol (total 10 µM; in 5:2:1 ratio). As shown in Figure 1B, simvastatin decreased ox-LDL induced LOX-1 expression. γ- and α-tocopherols also decreased LOX-1 expression (γ- > α-tocopherol). Most interestingly, the combination of tocopherols had a very potent effect- almost as much as simvastatin. Simvastatin, α-tocopherol, and the tocopherols combination had a very potent inhibitory effect- almost as much as simvastatin. SMC apoptosis is associated with plaque rupture and promotion of outward remodeling as plaques resulting in aneurysm formation (1). Hence we investigated the effect of statins and tocopherols on SMC apoptosis. Caspase-3 (western blotting, Figure 2B) and TUNEL staining (flow cytometry, Figure 2C) showed that while both γ- and α-tocopherols decreased this marker of apoptosis (γ-tocopherol > α-tocopherol), the tocopherols combination had a very potent inhibitory effect- again as much as simvastatin, on SMC apoptosis (Figure 2C).

We believe this is the first study that examined the effect of different tocopherol components and their combination on ox-LL uptake, LOX-1 expression, adhesion molecule expression and markers of apoptosis. γ-tocopherol was absent from almost all preparation of vitamin E used in clinical trials in the past. Its absence may be the basis for the negative results of vitamin E trials. Based on the aforementioned studies, we suggest that γ-tocopherol should be a major component of vitamin E preparations for evaluation in anti-oxidant trials in primary or secondary prevention of cardiovascular diseases which are thought to be causally related to oxidative stress.
