

## Surface area effect of porous silicon in the electrochemical hydrogen storage

**Dr saloua merazga**

Centre de Recherche en Technologie des Semi-conducteurs pour l'Energétique (CRTSE), Algiers, Algeria

### Abstract:

In order to increase the capacity of hydrogen storage of the porous silicon and the specific surface area, we prepared different type of porous silicon: nanoporous and mesoporous silicon by using electrochemical anodization. After that, we investigated this layers by: SEM microscopy, SIMS spectrometry, contact angle, cyclic voltammetry, electrochemical spectroscopy (EIS) and charge / discharge galvanostatic. The SIMS profiles at depth performed on PS layers before and after the hydrogen sorption show the increase of hydrogen concentration from  $3.5 \times 10^{-2}$  atm / cm<sup>3</sup> to  $6.8 \times 10^{-2}$  atm / cm<sup>3</sup> which confirms the sorption and the storage of H + ions in the anode(PS). The measured discharge capacity is of the order of 477 mAh / g with a coulombic efficiency of the order of 94% for the nanoporous silicon which confirms that this material is could be a promising candidate for the storage of hydrogen.
